S1. 3 LEVEL RAMAN TRANSFER WITH CROSS COUPLING

In our system, the separation in energy between the initial and target state is much smaller than the single photon detuning Δ from the intermediate state. Thus, there is significant cross coupling for the scattering rate and light shift, where each state is coupled to the excited state by the power in both beams. Under these conditions, the scattering rate and light shift is proportional to the total power $P_{\text{tot}} = P_m + P_a$, where $P_m(P_a)$ is the power in the beam that addresses the molecular (atomic) state. The Raman Rabi frequency is proportional to $\sqrt{P_m P_a}$. With a fixed total power and thus fixed scattering rate, the Raman Rabi frequency is maximized by maximizing $\sqrt{P_m(P_{\text{tot}} - P_m)}$, which is achieved when $P_m = P_a = P_{\text{tot}}/2$.

For the purposes of this work, we denote $\Omega_a(\Omega_m)$ as the Rabi frequencies to drive a transition from the atom (target molecule) state to the intermediate state used in the Raman transition corresponding to the power in a single beam, $P_a(P_m)$. Thus, the Raman Rabi frequency remains $\Omega_a\Omega_m/2\Delta$, where Δ is the single photon detuning. Cross coupling affects the scattering rate and light shift, and assuming equal powers in both beams, these quantities become $\Gamma_e\Omega_m^2/2\Delta^2 + \Gamma_e\Omega_a^2/2\Delta^2$ and $\Omega_m^2/2\Delta - \Omega_a^2/2\Delta$, where Γ_e is the excited state linewidth. Since $\Omega_m \gg \Omega_a$, the scattering rate and light shift can be approximated as $\Gamma_e\Omega_m^2/2\Delta^2$ and $\Omega_m^2/2\Delta$.

S2. RAMAN TRANSFER WITH MANY INTERMEDIATE STATES

With multiple intermediate states, the total Raman Rabi frequency, scattering rate, and light shift become a sum over all these possible states. In our model, we consider all vibrational states of $c^3\Sigma^+(\Omega = 1)$ as intermediate states, as well as states in the atomic continuum. The Rabi frequency between two states is proportional to the electronic dipole moment, arising from the electronic wavefunctions, and the vibrational wavefunction (in the relative motion coordinate of the two atoms) overlap between the two states. Under the assumption that the electronic dipole moment d is the same for all transitions between the ground state and the excited electronic state, the total Raman Rabi frequency becomes:

$$\Omega_R = \frac{d^2 E^2}{2\hbar^2} \sum_{v'} \frac{\langle a|v'\rangle \langle v'|m\rangle}{\Delta_{v'}} \quad (\text{S.1})$$

where $|a\rangle$ ($|m\rangle$) are the relative coordinate wavefunctions for the trapped atom (target-molecule) state, and $|v'\rangle$ is the relative coordinate wavefunction for the excited state which includes both bound molecule states and the atomic continuum. $\Delta_{v'}$ is a single photon detuning with respect to the $|v'\rangle$ state, E is the electric field for the power in the single beam given a waist size. We can divide this sum into a sum over all the bound molecular states, and a sum over atomic continuum states.

*Electronic address: yichaoyu@g.harvard.edu

†Electronic address: ni@chemistry.harvard.edu

$$\Omega_R = \frac{d^2 E^2}{2\hbar^2} \sum_{v' \leq v'_{\max}} \frac{\langle a|v' \rangle \langle v'|m \rangle}{\Delta_{v'}} + \frac{d^2 E^2}{2\hbar^2} \sum_{v' > v'_{\max}} \frac{\langle a|v' \rangle \langle v'|m \rangle}{\Delta_{v'}} \quad (\text{S.2})$$

where v'_{\max} corresponds to the most weakly bound electronically excited molecular state. The first term can be calculated numerically given an excited state potential. To calculate the second term, we first make an assumption that we are far enough detuned from the contributing continuum states that they are all at approximately the same detuning, δ_{thresh} . This allows us to pull it out of the sum, and we obtain:

$$\Omega_R \approx \frac{d^2 E^2}{2\hbar^2} \sum_{v' \leq v'_{\max}} \frac{\langle a|v' \rangle \langle v'|m \rangle}{\Delta_{v'}} + \frac{d^2 E^2}{2\hbar^2 \delta_{\text{thresh}}} \sum_{v' > v'_{\max}} \langle a|v' \rangle \langle v'|m \rangle \quad (\text{S.3})$$

From requiring orthogonality,

$$\sum_{v'} \langle a|v' \rangle \langle v'|m \rangle = \langle a|m \rangle = 0 \quad (\text{S.4})$$

we derive an expression for the second sum in equation [S.3](#)

$$\sum_{v' > v'_{\max}} \langle a|v' \rangle \langle v'|m \rangle = - \sum_{v' \leq v'_{\max}} \langle a|v' \rangle \langle v'|m \rangle \quad (\text{S.5})$$

which can be calculated from the vibrational states of the excited state potential. Thus, the Raman Rabi frequency can be approximated as:

$$\Omega_R \approx \frac{d^2 E^2}{2\hbar^2} \sum_{v' \leq v'_{\max}} \frac{\langle a|v' \rangle \langle v'|m \rangle}{\Delta_{v'}} - \frac{d^2 E^2}{2\hbar^2 \delta_{\text{thresh}}} \sum_{v' \leq v'_{\max}} \langle a|v' \rangle \langle v'|m \rangle \quad (\text{S.6})$$

We can account for the atomic continuum in the scattering rate in a similar way.

$$\Gamma_s = \frac{d^2 E^2}{2\hbar^2} \sum_{v' \leq v'_{\max}} \Gamma_{v'} \frac{\langle m|v' \rangle \langle v'|m \rangle}{\Delta_{v'}^2} + \frac{d^2 E^2}{2\hbar^2} \sum_{v' > v'_{\max}} \Gamma_{v'} \frac{\langle m|v' \rangle \langle v'|m \rangle}{\Delta_{v'}^2} \quad (\text{S.7})$$

$$\approx \frac{d^2 E^2}{2\hbar^2} \sum_{v' \leq v'_{\max}} \Gamma_{v'} \frac{\langle m|v' \rangle \langle v'|m \rangle}{\Delta_{v'}^2} + \frac{d^2 E^2 \Gamma}{2\hbar^2 \delta_{\text{thresh}}^2} \sum_{v' > v'_{\max}} \langle m|v' \rangle \langle v'|m \rangle \quad (\text{S.8})$$

where $\Gamma_{v'}$ is the excited state linewidth for the $|v' \rangle$ state, and we have assumed the atomic continuum states all have the same linewidth Γ . Using normalization, we derive an expression for the sum in the second term

$$\sum_{v' > v'_{\max}} \langle m|v' \rangle \langle v'|m \rangle = 1 - \sum_{v' \leq v'_{\max}} \langle m|v' \rangle \langle v'|m \rangle \quad (\text{S.9})$$

We then arrive at an expression for the scattering rate, accounting for the atomic continuum,

$$\Gamma_s \approx \frac{d^2 E^2}{2\hbar^2} \sum_{v' \leq v'_{\max}} \Gamma_{v'} \frac{\langle m|v' \rangle \langle v'|m \rangle}{\Delta_{v'}^2} + \frac{d^2 E^2 \Gamma}{2\hbar^2 \delta_{\text{thresh}}^2} \left(1 - \sum_{v' \leq v'_{\max}} \langle m|v' \rangle \langle v'|m \rangle \right) \quad (\text{S.10})$$

The effect of the continuum is to add an extra state at the atomic threshold with strength proportional to the amount of wavefunction overlap between the target-molecular state and all atomic continuum states. This term is especially important for our target-molecule state, because the square of the wavefunction overlap between the target-molecule state and all excited vibrational states is only 0.02

$$\sum_{v' \leq v'_{\max}} \langle m|v' \rangle \langle v'|m \rangle = 0.02 \quad (\text{S.11})$$

leading to strong scattering from the atomic continuum. We note that this model also leads to a component in the scattering rate that is proportional to $1/\delta_{\text{thresh}}^2$ and is smaller as one detunes farther from the threshold.

A very similar result holds for the light shift and is written here for completeness

$$\frac{d^2 E^2}{2\hbar^2} \sum_{v' \leq v'_{\max}} \frac{\langle m|v' \rangle \langle v'|m \rangle}{\Delta_{v'}} + \frac{d^2 E^2}{2\hbar^2 \delta_{\text{thresh}}} \left(1 - \sum_{v' \leq v'_{\max}} \langle m|v' \rangle \langle v'|m \rangle \right) \quad (\text{S.12})$$

S3. CALCULATING MATRIX ELEMENTS WITH COUPLED CHANNEL GROUND STATE

The free atom state (with spherically symmetric harmonic confinement) and target weakly-bound molecular state are calculated using coupled-channel methods. With the cylindrical symmetry present at non-zero magnetic field, the magnetic quantum number is a good quantum number. We use the $|F_{\text{Na}} = 2, m_{F_{\text{Na}}} = 2, F_{\text{Cs}} = 3, m_{F_{\text{Cs}}} = 3\rangle$ spin combination, so states with total $m_F = 5$ are included. These states, written in the basis $|S, m_S, I, m_I\rangle$, include $|0, 0, 5, 5\rangle, |1, 0, 5, 5\rangle, |1, 1, 5, 4\rangle, |1, 1, 4, 4\rangle$, where $S = 0, 1$ is the total electron spin and $I = 2, 3, 4, 5$ is the total nuclear spin.
